

# Algorithms for Streaming Data

Piotr Indyk

# Streaming Data

- Problems defined over points  $P = \{p_1, \dots, p_n\}$
- The algorithm sees  $p_1$ , then  $p_2$ , then  $p_3, \dots$
- Key fact: it has limited storage
  - Can store only  $s \ll n$  points
  - Can store only  $s \ll n$  bits (need to assume finite precision)

$p_1 \dots p_2 \dots p_3 \dots p_4 \dots p_5 \dots p_6 \dots p_7 \dots$

# Example - diameter

# Problems

- Diameter
- Minimum enclosing ball
- $l_2$  norm of a vector

# Diameter in $l_\infty^d$

- Assume we measure distances according to the  $l_\infty$  norm
- What can we do ?

# Diameter in $l_\infty$ , ctd.

- From previous lecture we know that  
 $\text{Diam}_\infty(P) = \max_{i=1 \dots d'} [\max_{p \in P} p_i - \min_{p \in P} p_i]$
- Can maintain max/min in constant space
- Total space =  $O(d')$
- What about  $l_1$  ?

# Diameter in $l_1$

- Let  $f:l_1^d \rightarrow l_\infty^{2^d}$  be an isometric embedding
- We will maintain  $\text{Diam}_\infty(f(P))$ 
  - For each point  $p$ , we compute  $f(p)$  and feed it to the previous algorithm
  - Return the pair  $p,q$  that maximizes  $\|f(p)-f(q)\|_\infty$
- This gives  $O(2^d)$  space for  $l_1^d$
- What about  $l_2$  ?

# Diameter in $l_2$

- Let  $f:l_2^d \rightarrow l_\infty^{d'}$ ,  $d'=O(1/\varepsilon)^{(d-1)/2}$ , be a  $(1+\varepsilon)$ -distortion embedding
- Apply the same algorithm as before
- Parameters:
  - Space:  $O(1/\varepsilon)^{(d-1)/2}$
  - Time: ?

# Minimum Enclosing Ball

- Problem: given  $P = \{p_1 \dots p_n\}$ , find center  $o$  and radius  $r > 0$  such that
  - $P \subseteq B(o, r)$
  - $r$  is as small as possible
- Solve the problem in  $l_\infty$
- Generalize to  $l_1$  and  $l_2$  via embeddings

# MEB in $l_\infty$

- Let  $C$  be the hyper-rectangle defined by max/min in every dimension
- Easy to see that min radius ball  $B(o,r)$  is a min size hypercube that contains  $C$
- Min radius = min side length/2
- How to solve it in  $l_2$  ?

# MEB in $l_2$

- Firstly, assume  $(1+\varepsilon) \approx 1$
- Let  $f: l_2^d \rightarrow l_\infty^{d'}$  be an “almost” isometric embedding
- Algorithm:
  - For each point  $p$ , compute  $f(p)$
  - Maintain  $\text{MEB}_\infty B'(o', r)$  of  $f(p_1) \dots f(p_n)$
  - Compute  $o$  such that  $f(o) = o'$
  - Report  $B(o, r)$

# Problem

- There might be NO  $o$  such that  $f(o)=o'$
- If it was the case, then we would always have MEB radius=Diameter/2, which is not true:

- The problem is that  $f$  is into, not onto

# The Correct Version

- Algorithm:
  - Maintain the min/max points  $f(p_1) \dots f(p_{2d'})$ , two points per dimension
  - Compute MEB  $B(o,r)$  of  $p_1 \dots p_{2d'}$
  - Report  $B(o,r)$

# Correctness

MEB radius for  $P$

= Min  $r$  s.t.  $\exists o \ P \subseteq B(o,r)$

$\approx$  Min  $r$  s.t.  $\exists o \ f(P) \subseteq B(f(o),r)$

= Min  $r$  s.t.  $\exists o \ \{f(p_1) \dots f(p_{2d'})\} \subseteq B(f(o),r)$  [see next slide]

$\approx$  Min  $r$  s.t.  $\exists o \ \{p_1 \dots p_{2d'}\} \subseteq B(o,r)$

= MEB radius for  $\{p_1 \dots p_{2d'}\}$

- Total error at most  $(1+\epsilon)^2$
- In reality, at most  $(1+\epsilon)$

# Digression: Core Sets

- In the previous slide we use the fact that in  $l_\infty$ , for any set  $P$  of points, there is a subset  $P'$  of  $P$ ,  $|P'|=2d'$ , such that  $MEB(P')=MEB(P)$
- $P'$  is called a “core-set” for the MEB of  $P$  in  $l_\infty$
- For more on core-sets, see the web page by [Sariel Har-Peled](#)

# Maintaining $l_2$ norm of a vector

- Implicit vector  $\mathbf{x}=(x_1, \dots, x_n)$
- Start with  $\mathbf{x}=0$
- Stream: sequence of pairs  $(i, b)$  , meaning
$$x_i = x_i + b$$
- Goal: maintain (approximately)  $\|\mathbf{x}\|_2$

# Motivation

- Consider a set of web pages, stored in some order
- Two pages are “similar” if they link to the same page
- Note that each page is similar to itself
- Want to know the number of pairs of similar web pages

# Connection to $l_2$ norm

- Let
  - $\text{In}(i)$  be the # in-links to page  $i$
  - $\text{Out}(i)$  be the # out-links of page  $i$
- $\text{Out}(i)$  is easy to compute,  $\text{In}(i)$  is not
- We want to compute
$$\frac{1}{2} * \sum_i \text{In}(i) (\text{In}(i)+1) = \frac{1}{2} [\sum_i \text{In}(i)^2 + \sum_i \text{In}(i)]$$
- Every time we see link to  $i$ :  $\text{In}(i) := \text{In}(i)+1$

# Approximate Algorithm

- We will use roughly  $O(\log(1/P)/\epsilon^2)$  numbers, where  $1-P$  is the probability of successful estimation

# Algorithm

- From JL lemma, it suffices to maintain  $Ax$  for “random”  $A$ , since  $\|Ax\| \approx \|x\|$
- Assume
  - we have  $Ax$
  - Need to compute  $Ay$ , where  $y=x$  except for  $y_i=x_i+b$
- Use linearity:
$$Ay = A(y-x)+Ax = A(be_i)+Ax = b a^i + Ax$$

# Pseudo-randomness

- In practice: use  $A[i,j]=\text{Normal}(\text{RND}(i,j))$
- In theory: one can use bounded space random generators to generate  $A$  using only  $O(\log n * \log(1/P)/\epsilon^2)$  random numbers
